STRUCTURAL DESIGN OF
SELF-ELEVATING UNITS
(LRFD METHOD)

OCTOBER 2004

*Since issued in print (October 2004), this booklet has been amended, latest in April 2007.
See the reference to "Amendments and Corrections" on the next page.*

DET NORSKE VERITAS

FOREWORD

DET NORSKE VERITAS (DNV) is an autonomous and independent foundation with the objectives of safeguarding life, property and the environment, at sea and onshore. DNV undertakes classification, certification, and other verification and consultancy services relating to quality of ships, offshore units and installations, and onshore industries worldwide, and carries out research in relation to these functions.

DNV Offshore Codes consist of a three level hierarchy of documents:

- *Offshore Service Specifications*. Provide principles and procedures of DNV classification, certification, verification and consultancy services.
- *Offshore Standards*. Provide technical provisions and acceptance criteria for general use by the offshore industry as well as the technical basis for DNV offshore services.
- *Recommended Practices*. Provide proven technology and sound engineering practice as well as guidance for the higher level Offshore Service Specifications and Offshore Standards.

DNV Offshore Codes are offered within the following areas:

- A) Qualification, Quality and Safety Methodology
- B) Materials Technology
- C) Structures
- D) Systems
- E) Special Facilities
- F) Pipelines and Risers
- G) Asset Operation
- H) Marine Operations
- J) Wind Turbines

Amendments and Corrections

This document is valid until superseded by a new revision. Minor amendments and corrections will be published in a separate document normally updated twice per year (April and October).

For a complete listing of the changes, see the "Amendments and Corrections" document located at: <http://webshop.dnv.com/global/>, under category "Offshore Codes".

The electronic web-versions of the DNV Offshore Codes will be regularly updated to include these amendments and corrections.

Comments may be sent by e-mail to rules@dnv.com

For subscription orders or information about subscription terms, please use distribution@dnv.com

Comprehensive information about DNV services, research and publications can be found at <http://www.dnv.com>, or can be obtained from DNV, Veritasveien 1, NO-1322 Høvik, Norway; Tel +47 67 57 99 00, Fax +47 67 57 99 11.

If any person suffers loss or damage which is proved to have been caused by any negligent act or omission of Det Norske Veritas, then Det Norske Veritas shall pay compensation to such person for his proved direct loss or damage. However, the compensation shall not exceed an amount equal to ten times the fee charged for the service in question, provided that the maximum compensation shall never exceed USD 2 million.
In this provision "Det Norske Veritas" shall mean the Foundation Det Norske Veritas as well as all its subsidiaries, directors, officers, employees, agents and any other acting on behalf of Det Norske Veritas.

Main changes

- **General**

The present edition supersedes the January 2001 edition.

- **Main changes**

The main changes are:

- Sec.1 has been aligned with other relevant structural standards (e.g. references, terminology, definitions, etc.) and with DNV-OS-C101.
- Definition and application of *design temperature* have been updated. The term *service temperature* has been introduced.

- Formulations relating to *tank pressures* have been simplified and clarified.
- Text regarding redundancy and detailed design are modified and moved to Sec.3.
- Formulation relating to sea pressure during transit have been simplified and clarified.

Corrections and Clarifications

In addition to the above mentioned changes, a number of corrections and clarifications have been made to the existing text.

SECTION 1 INTRODUCTION

A. General

A 100 Introduction

101 This standard provides principles, technical requirements and guidance for the design and construction of self-elevating units.

102 This standard is based on the load and resistance factor design (LRFD). LRFD is defined in DNV-OS-C101.

103 Self-elevating units may alternatively be designed according to working stress design principles, which is defined in DNV-OS-C201.

104 The standard has been written for general world-wide application. Coastal State regulations may include requirements in excess of the provisions of this standard depending on size, type, location and intended service of the offshore unit/installation.

A 200 Objectives

201 The objectives of this standard are to:

- provide an internationally acceptable standard of safety for self-elevating units by defining minimum requirements for the structural design, materials and construction
- serve as a technical reference document in contractual matters between purchaser and manufacturer
- serve as a guideline for designers, purchasers, contractors and regulators.
- specify procedures and requirements for units and installations subject to DNV verification and classification services.

A 300 Scope and application

301 This standard applies to all types of self-elevating units constructed in steel.

302 All marine operations shall, as far as practicable, be based upon well-proven principles, techniques, systems and equipment and shall be undertaken by qualified, competent personnel possessing relevant experiences.

303 A self-elevating unit is designed to function in a number of modes, e.g. transit, operational and survival. Design criteria for the different modes shall define and include relevant consideration of the following items:

- intact condition, structural strength
- damaged condition, structural strength
- fatigue strength
- accidental damage
- air gap
- overturning stability
- watertight integrity and hydrostatic stability.

Limiting design criteria when going from one mode to another shall be established and clearly documented.

Watertight integrity and hydrostatic stability shall comply with requirements given in DNV-OS-C301.

304 For novel designs, or unproven applications of designs where limited or no direct experience exists, relevant analyses and model testing, shall be performed which clearly demonstrate that an acceptable level of safety is obtained.

305 Requirements concerning riser systems are not consid-

ered in this standard.

306 Structural design covering marine operation sequences is not covered in this standard and shall be undertaken in accordance with the requirements stated in Rules for Planning and Execution of Marine Operations.

A 400 Classification

401 Principles, procedures and applicable class notations for classification of offshore units are given in the DNV Offshore Service Specifications listed in Table A1. These refer to the present standard for structural requirements related to self-elevating units.

Table A1 DNV Offshore Service Specifications	
Reference	Title
DNV-OSS-101	Rules for Classification of Drilling and Support Units
DNV-OSS-102	Rules for Classification of Floating Production, Storage and Loading Units

402 Documentation for classification shall be in accordance with the NPS DocReq (DNV Nauticus Production System for documentation requirements) and Guideline No.17.

403 Technical requirements given in DNV-OS-C101 Sec.8, related to Serviceability Limit States, are not mandatory as part of classification.

404 Technical requirements given in DNV-OS-C101 related to design for earthquakes are not mandatory as part of classification.

B. References

B 100 Offshore standards

101 The standards listed in Table B1 include provisions, which through reference in this text constitute provisions for this standard.

102 Other recognised standards may be used provided it is demonstrated that these meet or exceed the requirements of the standards referenced in Table B1.

C. Definitions

C 100 Verbal forms

101 Shall: Indicates a mandatory requirement to be followed for fulfilment or compliance with the present standard. Deviations are not permitted unless formally and rigorously justified, and accepted by all relevant contracting parties.

102 Should: Indicates a recommendation that a certain course of action is preferred or particularly suitable. Alternative courses of action are allowable under the standard where agreed between contracting parties but shall be justified and documented.

103 May: Indicates a permission, or an option, which is permitted as part of conformance with the standard.

C 200 Terms

201 Self-elevating unit or jack-up: A mobile unit having hull with sufficient buoyancy to transport the unit to the desired location, and that is bottom founded in its operation mode. The unit reaches its operation mode by lowering the legs to the seabed and then jacking the hull to the required elevation.

202 Moulded baseline: A horizontal line extending through the upper surface of hull bottom shell.

203 Installation condition: A condition during which a unit is lowering the legs and elevating the hull.

204 Operating conditions: Conditions wherein a unit is on location for purposes of drilling or other similar operations, and combined environmental and operational loadings are within the appropriate design limits established for such operations. The unit is supported on the seabed.

205 Retrieval conditions: Conditions during which a unit is lowering the hull and elevating the legs.

206 Survival conditions: Conditions wherein a unit is on location subjected to the most severe environmental loadings for which the unit is designed. Drilling or similar operations may have been discontinued due to the severity of the environmental loadings. The unit is supported on the seabed.

207 Transportation or transit conditions: All unit movements from one geographical location to another.

208 Field move: A wet transit that would require no more than a 12-hour voyage to a location where the unit could be elevated, or to a protected location.

209 Ocean transit: A wet transit that would require more

than a 12-hour voyage to a location where the unit could be elevated, or to a protected location.

210 Dry transit: A transit where the unit is transported on a heavy lift unit.

211 Wet transit: A transit where the unit is floating during the move.

212 Sustained wind velocity: The average wind velocity during a time interval (sampling time) of 1 minute. The most probable highest sustained wind velocity in a period of N years will be referred to as the «N years sustained wind». This is equivalent to a wind velocity with a recurrence period of N years.

213 Gust wind velocity: The average wind velocity during a time interval of 3 s. The «N years gust wind velocity» is the most probable highest gust velocity in a period of N years.

214 One hour wind velocity: The average wind velocity during a time interval of one hour.

D. Abbreviations and Symbols

D 100 Abbreviations

101 Abbreviations used in this standard are given in DNV-OS-C101 or in Table D1.

Table D1 Abbreviations	
Abbreviation	In full
LAT	Lowest astronomical tide
MWL	Mean still water level
SNAME	Society of Naval Architects and Marine Engineers

D 200 Symbols

201 Latin characters:

a_h	=	horizontal acceleration
a_v	=	vertical acceleration
\bar{a}	=	the intercept of the design S-N curve with the log N axis
g_0	=	acceleration due to gravity
h	=	the shape parameter of the Weibull stress range distribution
h_{op}	=	vertical distance from the load point to the position of maximum filling height
k	=	the roughness height
m	=	inverse slope of the S-N curve
n_i	=	the number of stress variations in i years appropriate to the global analysis.
n_0	=	total number of stress variations during the lifetime of the structure
p_d	=	design pressure
p_{dyn}	=	pressure head due to flow through pipes
p_e	=	dynamic pressure
p_s	=	static pressure
q_d	=	critical contact pressure of spudcan
z_b	=	vertical distance from moulded baseline to load point
A	=	area of spudcan in contact with seabed
C_D	=	drag coefficient
C_M	=	inertia coefficient
C_S	=	shape coefficient
D	=	member diameter
D_B	=	depth of barge

F_V	=	maximum design axial load in one leg (without load factors)
F_{Vd}	=	maximum design axial load in one leg (with load factors)
F_{VP}	=	minimum required pre-load on one leg
H_S	=	significant wave height
K_C	=	Keulegan-Carpenter number
L	=	length or breadth of barge
M	=	mass of unit, cargo, equipment or other components
M_{ed}	=	maximum design eccentricity moment
M_O	=	overturning moment
M_S	=	stabilising moment
M_U	=	minimum design moment restraint of the leg at the seabed
P	=	static axial load on one leg
P_E	=	Euler buckling load for one leg
P_{Hd}	=	horizontal design force on heavy component
P_{Vd}	=	vertical design force on heavy component
R	=	equivalent radius of spudcan contact area

T	=	wave period
T_{TH}	=	transit draught
T_Z	=	zero-upcrossing period
U_m	=	the maximum orbital particle velocity

202 Greek characters:

α	=	amplification factor for leg bending response
$\Delta\sigma_{n0}$	=	extreme stress range that is exceeded once out of n_0 stress variations
$\Delta\sigma_{ni}$	=	extreme stress range that is exceeded once out of n_i stress variations.
ρ	=	density
$\gamma_{f,D}$	=	partial load factor for deformation loads
$\gamma_{f,E}$	=	partial load factor for environmental loads
$\gamma_{f,G,Q}$	=	partial load factor for permanent loads
γ_M	=	material factor for steel
γ_s	=	safety coefficient against overturning

SECTION 2

STRUCTURAL CATEGORISATION, MATERIAL SELECTION AND INSPECTION PRINCIPLES

A. General

A 100 Scope

101 This section describes the structural categorisation, selection of steel materials and inspection principles to be applied in design and construction of self-elevating units.

102 The structural application categories are determined based on the structural significance, consequences of failure and the complexity of the joints. The structural application categories set the selection of steel quality and the inspection extent of the welds.

103 The steel grades selected for structural components shall be related to calculated stresses and requirements for toughness properties and shall be in compliance with the requirements given in DNV-OS-B101 and DNV-OS-C101.

B. Structural Categorisation

B 100 Structural categorisation

101 Application categories for structural components are defined in DNV-OS-C101 Sec.4. Structural members of self-elevating units are grouped as follows:

Special category

- 1) Vertical columns in way of intersection with the mat structure.
- 2) Highly stressed elements of bottom of leg, including leg connection to spudcan or mat.
- 3) Intersections of lattice type leg structure that incorporates novel construction, including the use of steel castings.
- 4) Highly stressed elements of guide structures, jacking and locking system(s), jackhouse and support structure.
- 5) Highly stressed elements of crane pedestals, etc. and their supporting structure.

Guidance note:

Highly stressed elements are normally elements utilised more than 85% of the allowable structural capacity.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

Primary category

- 1) Combination of bulkhead, deck, side and bottom plating within the hull which form «Box» or «I» type main supporting structure.
- 2) All components of lattice type legs and external plating of cylindrical legs.
- 3) Jackhouse supporting structure and bottom footing structure that receives initial transfer of load from legs.
- 4) Internal bulkheads, shell and deck of spudcan or bottom mat supporting structures which are designed to distribute major loads, either uniform or concentrated, into the mat structure.
- 5) Main support structure of heavy substructures and equipment e.g. cranes, drill floor substructure, lifeboat platform and helicopter deck.

Secondary category

- 1) Deck, side and bottom plating of hull except areas where the structure is considered for primary or special application.
- 2) Bulkheads, stiffeners, decks and girders in hull that are not considered as primary or special application.
- 3) Internal bulkheads and girders in cylindrical legs.
- 4) Internal bulkheads, stiffeners and girders of spudcan or bottom mat supporting structures except where the structures are considered primary or special application.

C. Material Selection

C 100 General

101 Material specifications shall be established for all structural materials. Such materials shall be suitable for their intended purpose and have adequate properties in all relevant design conditions. Material selection shall be undertaken in accordance with the principles given in DNV-OS-C101.

102 When considering criteria appropriate to material grade selection, adequate consideration shall be given to all relevant phases in the life cycle of the unit. In this connection there may be conditions and criteria, other than those from the in-service, operational phase, that provide the design requirements in respect to the selection of material. (Such criteria may, for example, be design temperature and/or stress levels during marine operations.)

103 In 'special areas' structural cross-joints essential for the overall structural integrity where high tensile stresses are acting perpendicular to the plane of the plate, the plate material shall be documented with proven through thickness properties, e.g. by utilising Z-quality steel.

104 Material designations are defined in DNV-OS-C101 Sec.4.

C 200 Design and service temperatures

201 The design temperature for a unit is the reference temperature for assessing areas where the unit may be transported, installed and operated. The design temperature shall be lower or equal to the *lowest mean daily temperature* in air for the relevant areas. For seasonal restricted operations the *lowest mean daily temperature* in air for the season may be applied.

202 The service temperatures for different parts of a unit apply for selection of structural steel. The service temperatures are defined as presented in 203 to 206. In case different service temperatures are defined in 203 to 206 for a structural part the lower specified value shall be applied.

203 External structures above the lowest astronomical tide (LAT) for the unit in elevated operation or above the light transit waterline during transportation shall not be designed for a service temperature higher than the design temperature for the unit.

204 External structures below the lowest astronomical tide (LAT) during elevated operation and below the light transit waterline during transportation need not to be designed for service temperatures lower than 0°C.

205 Internal structures of mats, spudcans, legs and hull shall have the same service temperature as the adjacent external

structure if not otherwise documented.

206 Internal structures in way of permanently heated rooms need not be designed for service temperatures lower than 0°C.

C 300 Selection of structural steel

301 The grade of steel to be used is in general to be related to the service temperature and thickness as shown in the tables in DNV-OS-C101, Sec.4 for the various application categories.

302 When a stress relieving heat treatment is carried out after welding a steel grade may be considered for a lower service temperature than stipulated in the table.

303 For areas subjected to compressive and/or low tensile stresses, consideration may be given to the use of lower steel grades than stated in the tables of DNV-OS-C101 Sec.4.

304 The toughness requirements for steel plates, sections and weldments exceeding the thickness limits in the table shall be evaluated in each separate case.

305 Grade of steel to be used for thicknesses less than 10 mm and/or design temperature above 0 °C should be specially considered in each case.

306 Use of steels in anaerobic conditions or steels susceptible to hydrogen induced stress cracking (HISC) should be specially considered as specified in DNV-OS-C101 Sec.4.

D. Inspection Categories

D 100 General

101 Welding and the extent of non-destructive examination during fabrication, shall be in accordance with the requirements stipulated for the appropriate inspection category as defined in DNV-OS-C101.

102 Inspection categories determined in accordance with DNV-OS-C101, Sec.4 provide requirements for the minimum extent of required inspection.

Guidance note:

When considering the economic consequence that repair may entail, for example, in way of complex connections with limited or difficult access, it may be considered prudent engineering practice to require more demanding requirements for inspection than the required minimum.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

103 When determining the extent of inspection, and the locations of required NDT, in addition to evaluating design parameters (for example fatigue utilisation), consideration should be given to relevant fabrication parameters including:

- location of block or section joints
- manual versus automatic welding
- start and stop of weld etc.

SECTION 3 DESIGN PRINCIPLES

A. Introduction

A 100 General

101 The structure shall be designed according to the LRFD method with limit states and design conditions as described in the present standard. A general description of the format of LRFD method is given in DNV-OS-C101.

102 Relevant load combinations are to be established for the various design conditions and limit states based on the most unfavourable combinations of functional loads, environmental loads and/or accidental loads.

103 Modelling and analysis of the structure shall satisfactorily simulate the behaviour of the actual structure, including its supporting system, and the relevant environmental conditions. Reasonable simplifications may be introduced as a part of structural idealisation.

104 Limiting environmental and operating conditions (design data) for the different design conditions are to be specified by the builder.

105 Requirements regarding certification of jacking gear machinery are given in DNV-OS-D101.

106 The effect of earthquakes may be of significance for operations of self-elevating units in some regions. For loads and design against seismic events see DNV-OS-C101 and Sec.1 A404.

A 200 Overall design

201 The overall structural safety is to be evaluated on the basis of preventive measures against structural failure put into design, fabrication and in-service inspection as well as the unit's residual strength against total collapse in the case of structural failure of vital elements.

For vital elements, which are designed according to criteria given for intact structure, the likelihood and consequence of failure should be considered as part of the redundancy evaluations. The consequence of credible accidental events shall be documented according to the ALS, see Sec.7.

202 When determining the overall structural design, particular care shall be taken such that the solution does not lead to unnecessarily complicated connections.

A 300 Details design

301 Structural connections should, in general, be designed with the aim to minimise stress concentrations and reduce complex stress flow patterns. Connections should be designed with smooth transitions and proper alignment of elements. Large cut-outs should be kept away from flanges and webs of primary girders in regions with high stresses.

302 Transmission of tensile stresses through the thickness of plates should be avoided as far as possible. In cases where transmission of tensile stresses through the thickness cannot be avoided, structural steel with improved through thickness properties may be required, see Sec.2 C.

303 Units intended for operations in cold areas shall be so arranged that water cannot be trapped in local structures or machinery exposed to the ambient temperature.

304 If the unit is intended to be dry-docked the footing structure (i.e. mat or spudcans) shall be suitably strengthened to withstand associated loads.

B. Design Conditions

B 100 Basic conditions

101 The following design conditions, as defined in Sec.1 C, shall be considered as relevant for the unit:

- transit condition(s)
- installation condition
- operating condition(s)
- survival condition
- retrieval condition.

B 200 Transit

201 The present standard considers requirements for wet transits, i.e. field moves or ocean transits as defined in Sec.1 C. Requirements in case of dry transit on a heavy lift vessel are considered to be covered by the warranty authority for the operation.

202 A detailed transportation assessment shall be undertaken for wet transits. The assessment should include determination of the limiting environmental criteria, evaluation of intact and damage stability characteristics, motion response of the global system and the resulting, induced loads. The occurrence of slamming loads on the structure and the effects of fatigue during transport phases shall be evaluated when relevant.

Guidance note:

For guidance on global analysis for the transit condition see Classification Note 31.5 Sec.5.3 and for environmental loading see Classification Note 30.5.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

203 The structure may be analysed for zero forward speed in analysis of wet transits.

204 The legs are to be designed for the static and inertia forces resulting from the motions in the most severe environmental transit conditions, combined with wind forces resulting from the maximum wind velocity.

205 The leg positions for both field moves and ocean moves shall be assessed when considering structural strength for transit condition.

206 In lieu of a more accurate analysis, for the ocean transit condition the legs shall be designed for the following forces considered to act simultaneously:

- 120% of the acceleration forces caused by the roll and pitch of the unit
- 120% of the static forces at the maximum amplitude of roll or pitch
- wind forces from a 45 m/s wind velocity.

Guidance note:

The effect of heave, surge and sway are implicitly accounted for by use of the 20% upscaling of the motions.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

207 For the field move position the legs may be designed for the acceleration forces caused by a 6 degree single amplitude roll or pitch at the natural period of the unit plus 120% of the static forces at a 6 degree inclination of the legs unless otherwise verified by model tests or calculations.

208 Dynamic amplification of the acceleration forces on the legs is to be accounted for if the natural periods of the legs are such that significant amplification may occur.

209 If considered relevant, the effect of vortex shedding

induced vibrations of the legs due to wind is to be taken into account.

Guidance note:

For guidance relating to vortex induced oscillations see Classification Note 30.5 Sec.7.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

210 The hull shall be designed for global mass and sea pressure loads, local loads and leg loads during transit.

211 Satisfactory compartmentation and stability during all floating operations shall be ensured, see DNV-OS-C301.

212 Unless satisfactory documentation exists demonstrating that shimming is not necessary, relevant leg interfaces (e.g. leg and upper guide) are to be shimmed in the transit condition.

213 All aspects of transportation, including planning and procedures, preparations, seafastenings and marine operations should comply with the requirements of the warranty authority.

214 The structural strength of the hull, legs and footings during transit shall comply with the ULS, FLS and ALS given in Sec.5, Sec.6 and Sec.7, respectively .

B 300 Installation and retrieval

301 Relevant static and dynamic loads during installation and retrieval shall be accounted for in the design, including consideration of the maximum environmental conditions expected for the operations and leg impact on the seabed.

Guidance note:

Guidance relating to simplified analytical methodology for bottom impact on the legs is given in Classification Note 31.5 Sec.5.8.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

302 The capacity of the unit during pre-loading must be assessed. The purpose of pre-loading is to develop adequate foundation capacity to resist the extreme vertical and horizontal loadings. The unit should be capable of pre-loading to exceed the maximum vertical soil loadings associated with the worst storm loading.

Guidance note:

Guidance relating to pre-loading is given in Classification Note 30.4 Sec.1 and Sec.8.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

303 The hull structure shall be analysed to ensure it can withstand the maximum pre-loading condition.

304 The structural strength of the hull, legs and footings during installation and retrieval shall comply with the ULS given in Sec.5.

B 400 Operation and survival

401 The operation and survival conditions cover the unit in the hull elevated mode.

402 A detailed assessment shall be undertaken which includes determination of the limiting soils, environmental and mass criteria and the resulting, induced loads.

403 Dynamic structural deflection and stresses due to wave loading is to be accounted for if the natural periods of the unit are such that significant dynamic amplification may occur.

404 Non-linear amplification (large displacement effects) of the overall deflections due to second order bending effects of the legs are to be accounted for whenever significant.

405 The effect of leg fabrication tolerances and guiding system clearances are to be accounted for.

406 The leg/soil interaction is to be varied as necessary within the design specifications to provide maximum stress in

the legs, both at the bottom end and at the jackhouse level.

407 Critical aspects to be considered in the elevated condition are structural strength, overturning stability and air gap.

408 The structural strength of the hull, legs and footings during operation and survival shall comply with the ULS, FLS and ALS given in Sec.5, Sec.6 and Sec.7. The ULS assessment should be carried out for the most limiting conditions with the maximum storm condition and maximum operating condition examined as a minimum.

Guidance note:

The hull will typically comprise the following elements:

- decks
- sides and bottom plating
- longitudinal bulkheads
- transverse frames
- longitudinal girders and stringers
- stringers and web frames on the transverse bulkheads
- jackhouses.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

409 The strength of the hull shall be assessed based on the characteristic load conditions that result in maximum longitudinal tension and compression stresses (for yield and buckling assessment) in deck and bottom plating.

410 The effect of large openings in the hull (e.g. drill slot) that affect the distribution of global stresses should be determined by a finite element model accounting for three dimensional effects.

C. Environmental Conditions

C 100 General

101 All environmental phenomena that may contribute to structural damages are to be considered. Such phenomena are wind, waves, currents, ice, earthquake, soil conditions, temperature, fouling, corrosion, etc.

102 The specified environmental design data used for calculating design loads for intact structure are to correspond with the most probable largest values for a return period of 100 years, see DNV-OS-C101.

103 For damaged structure calculations a return period of one year is to be used, see DNV-OS-C101.

104 The environmental design data may be given as maximum wave heights with corresponding periods and wind- and current velocities and design temperatures or as acceptable geographical areas for operation. In the latter case the builder is to specify the operational areas and submit documentation showing that the environmental data for these areas are within the environmental design data.

105 The statistical data used as a basis for design must cover a sufficiently long period of time.

C 200 Wind

201 Wind velocity statistics are to be used as a basis for a description of wind conditions, if such data are available. Sustained, gust, and one hour wind are defined in Sec.1 C.

202 Characteristic wind design velocities are to be based upon appropriate considerations of velocity and height profiles for the relevant averaging time.

Guidance note:

Practical information in respect to wind conditions, including velocity and height profiles, is documented in Classification Note 30.5.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

203 When wind tunnel data obtained from reliable and ade-

quate tests on a representative model of the unit are available, these data will be considered for the determination of pressures and resulting forces.

C 300 Waves

301 Wave conditions which are to be considered for design purposes, may be described either by deterministic (regular) design wave methods or by stochastic (irregular seastate) methods applying wave energy spectra.

302 Short term irregular seastates are described by means of wave energy spectra that are characterised by significant wave height (H_S), and average zero-upcrossing period (T_Z).

Analytical spectrum expressions are to reflect the width and shape of typical spectra for the considered height.

The shortcrestedness of waves in a seaway, i.e. the directional dispersion of wave energy, may be taken into account. The principal direction of wave encounter is defined as the direction of maximum wave energy density.

Guidance note:

For open sea locations the Pierson-Moskowitz (P-M) type of spectrum may be applied. For shallow water, or locations with a narrow "fetch", a more narrow spectrum should be considered (e.g. Jonswap spectrum).

Practical information in respect to wave conditions is documented in Classification Note 30.5 Sec.3 and Classification Note 31.5 Sec.3.2.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

303 The long term behaviour of the sea is described by means of a family of wave spectra, the probability of occurrence for each spectrum being taken into account.

304 For this purpose one needs the joint probability density function for H_S and T_Z , which may be obtained from wave statistics. A description of the long term seastates based on the use of hindcastings may also be accepted. Wave statistics for individual principal directions of wave encounter should be used, otherwise conservative assumptions are to be introduced.

Extreme wave heights are expressed in terms of wave heights having a low probability of occurrence.

The « N year wave height» is the most probable largest individual wave height during N years. This is equivalent to a wave height with a return period of N years.

305 In deterministic design procedures, based on regular wave considerations, the wave is to be described by the following parameters:

- wave period
- wave height
- wave direction
- still water depth.

The choice of an appropriate design wave formulation has to be based on particular considerations for the problem in question. Shallow water effects are to be accounted for.

306 The design waves are to be those that produce the most unfavourable loads on the considered structure, taking into account the shape and size of structure, etc.

The wave period is to be specified in each case of application. It may be necessary to investigate a representative number of wave periods, in order to ensure a sufficiently accurate determination of the maximum loads.

C 400 Current

401 Adequate current velocity data are to be selected from the statistics available. Different components of current are to be considered, such as tidal current and wind generated current.

402 The variation of current velocity over the water depth is

to be considered when this is relevant.

C 500 Temperature

501 The design temperature shall be specified as necessary for the areas where the unit is to operate or be transported, Sec.2 C200.

C 600 Snow and ice

601 Snow and ice shall be considered as necessary for the areas where the unit is to operate or be transported.

D. Method of Analysis

D 100 General

101 Structural analysis shall be performed to evaluate the structural strength due to global and local effects.

102 The following responses shall be considered in the structural design whenever significant:

- dynamic stresses for all limit states
- non-linear wave loading effects, (e.g. effect of drag and finite wave elevation)
- non-linear amplification due to second order bending effects of the legs (P-delta effect)
- effects of leg fabrication tolerances and leg guiding system clearances
- slamming induced vibrations
- vortex induced vibrations (e.g. resulting from wind loads on structural elements in a flare tower or in lattice legs above jackhouses)
- friction and wear (e.g. at leg guiding system or at riser system interfaces with hull structures).

103 Non-linear amplification of the overall deflections due to second order bending effects of the legs are to be accounted for whenever significant. The non-linear bending response may be calculated by multiplying the linear leg response by an amplification factor as follows:

$$\alpha = \frac{1}{1 - P/P_E}$$

P = static axial load on one leg

P_E = Euler buckling load for one leg.

104 In the unit elevated mode the global structural behaviour may be calculated by deterministic quasi-static analysis, directly considering non-linear wave and leg bending effects. The effect of dynamics should be represented by an inertia force contribution at the level of the hull centre of gravity or by a dynamic amplification factor, as specified in Classification Note 31.5.

105 In case of significant uncertainties related to the non-linear, dynamic behaviour, stochastic time domain analysis may be performed. The selection of critical seastate for the analysis should be properly considered.

Guidance note:

For shallow waters the significant wave height should be corrected as shown in Classification Note 30.5 Sec.3.2.11.

The irregular wave simulation may be performed as presented in Classification Note 30.5 Sec.3.2.12.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

106 Where non-linear loads may be considered as being insignificant, or where such loads may be satisfactorily accounted for in a linearised analysis, a frequency domain analysis may be undertaken. Transfer functions for structural response shall be established by analysis of an adequate

number of wave directions, with an appropriate radial spacing. A sufficient number of periods shall be analysed to:

- adequately cover the site specific wave conditions
- to satisfactorily describe transfer functions at, and around, the wave 'cancellation' and 'amplifying' periods
- to satisfactorily describe transfer functions at, and around, the resonance period of the unit.

107 As an alternative to time domain analysis model testing may be performed when non-linear effects cannot be adequately determined by direct calculations. Model tests should also be performed for new types of self-elevating units.

108 For independent leg units, the static inclination of the legs is to be accounted for. The inclination is defined as the static angle between the leg and a vertical line and may be due to fabrication tolerances, fixation system and hull inclination, as specified in Classification Note 31.5.

109 The seabed conditions, and therefore the leg and soil interaction, need to be considered as it affects the following:

- leg bending moment distribution
- overall structure stiffness and therefore the natural period of the unit
- load distribution on the spudcans.

The leg and soil interaction should be varied as necessary between an upper and lower bound to provide conservative response limits at the bottom leg and footing area and at the jackhouse level.

Guidance note:

As the leg and soil interaction is difficult to predict, it is acceptable and conservative to assume pinned and fixed conditions as the upper and lower bounds.

For further guidance see Classification Note 30.4 Sec.8 and Classification Note 31.5, Sec.3.6 and Sec.5.5.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

110 The leg and hull connection may be designed by any of or combination of the following methods:

- a fixation system, i.e. rack chock
- a fixed jacking system, i.e. pinions rigidly mounted to the jackhouse
- a floating jacking system, i.e. pinions mounted to the jackhouse by means of flexible shock pads
- a guiding system by upper and lower guides.

The characteristics and behaviour of the actual leg and hull connection system need to be properly represented in the appropriate global and local analyses.

Guidance note:

Practical information in respect to modelling leg and hull interaction is documented in Classification Note 31.5 Sec.5.4 or SNAME 5-5A, Section 5.6.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 200 Global structural models

201 A global structural model shall represent the global stiffness and behaviour of the unit. The global model should usually represent the following.:

- footing main plating and stiffeners
- leg truss or shell and stiffeners
- jackhouse and leg/hull interaction
- main bulkheads, frameworks and decks for the deck structure ("secondary" decks which are not taking part in the global structural capacity should not be modelled)

— mass model.

202 Depending on the purpose of the analysis and possible combination with further local analysis the different level of idealisation and detailing may be applied for a global structure. The hull may either be represented by a detailed plate and shell model or a model using grillage beams. The legs may be modelled by detailed structural models or equivalent beams, or a combination of such.

Guidance note:

For further guidance regarding modelling procedures see Classification Note 31.5 or SNAME 5-5A.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 300 Local structural models

301 An adequate number of local structural models should be created in order to evaluate response of the structure to variations in local loads. The model(s) should be sufficiently detailed such that resulting responses are obtained to the required degree of accuracy. A number of local models may be required in order to fully evaluate local response at all relevant sections.

The following local models should be analysed in the evaluation of ULS:

- footing, mat or spudcan
- stiffened plates subjected to tank pressures or deck area loads
- leg and hull connection system including jackhouse support structure
- support structure for heavy equipment such as drill floor and pipe racks
- riser hang off structure
- crane pedestal support structure
- helicopter deck support structure.

302 A detailed finite element model should be applied to calculate the transfer of leg axial forces, bending moments and shears between the upper and lower guide structures and the jacking and/or fixation system. The systems and interactions should be properly modelled in terms of stiffness, orientation and clearances. The analysis model should include a detailed model of the leg in the hull interface area, the guides, fixation and/or jacking system, together with the main jackhouse structure.

Guidance note:

The detailed leg model should normally extend 4 bays below and above the lower and upper guides, respectively.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

Guidance note:

For further guidance regarding modelling procedures see Classification Note 31.5 or SNAME 5-5A.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 400 Fatigue analysis

401 The fatigue life shall be calculated considering the combined effects of global and local structural response. The expected dynamic load history shall be specified in the design brief as basis for the calculations.

402 Stress concentration factors for fatigue sensitive structural details that cannot be obtained from standard tables, e.g. due to different structural arrangement or that dimensions are out of range of the formula, shall be determined by a finite element analysis.

SECTION 4 DESIGN LOADS

A. Introduction

A 100 General

101 The requirements in this section define and specify load components and load combinations to be considered in the overall strength analysis as well as design pressures applicable in formulae for local scantlings.

102 Characteristic loads shall be used as reference loads. General description of load components and combinations are given in DNV-OS-C101. Details regarding environmental loads are described in Classification Note 30.5. Presentation of load categories relevant for self-elevating units are given in B to H.

B. Permanent Loads

B 100 General

101 Permanent loads are loads that will not vary in magnitude, position, or direction during the period considered and include:

- 'lightweight' of the unit, including mass of permanently installed modules and equipment, such as accommodation, helicopter deck, drilling and production equipment
- permanent ballast
- hydrostatic pressures resulting from buoyancy
- pretension in respect to drilling and production systems (e.g. risers, etc.).

C. Variable Functional Loads

C 100 General

101 Variable functional loads are loads that may vary in magnitude, position and direction during the period under consideration.

102 Except where analytical procedures or design specifications otherwise require, the value of the variable loads utilised in structural design should be taken as either the lower or upper design value, whichever gives the more unfavourable effect. Variable functional loads on deck areas may be found in DNV-OS-C101, Sec.3. These should be applied unless specified otherwise in design basis or design brief.

103 Variations in operational mass distributions (including variations in tank load conditions) shall be adequately accounted for in the structural design.

104 Design criteria resulting from operational requirements should be fully considered. Examples of such operations may be:

- drilling, production, workover, and combinations thereof
- consumable re-supply procedures
- maintenance procedures
- possible mass re-distributions in extreme conditions.

105 Dynamic loads resulting from flow through air pipes during filling operations shall be adequately considered in the design of tank structures.

C 200 Lifeboat platforms

201 Lifeboat platforms shall be checked for ULS and ALS if

relevant. A dynamic factor of 0.2 g_0 due to retardation of the lifeboats when lowered shall be included.

C 300 Tank loads

301 A minimum design density (ρ) of 1.025 t/m³ should be considered in the determination of the appropriate scantlings of tank arrangements.

302 The extent to which it is possible to fill sounding, venting or loading pipe arrangements shall be fully accounted for in determination of the maximum design pressure which a tank may be subjected to.

303 Dynamic pressure heads resulting from the filling of such pipes shall be included in the design pressure head where such load components are applicable.

304 All tanks shall be designed for the following internal design pressure:

$$P_d = \rho g_0 h_{op} \left(\gamma_{f,G,Q} + \frac{a_v}{g_0} \gamma_{f,E} \right) \quad (\text{kN/m}^2)$$

h_{op} = vertical distance (m) from the load point to the position of maximum filling height. For tanks adjacent to the sea and situated below the extreme operational draught (T_E) during wet transit, h_{op} should not be taken less than the distance from the load point to the static sea level.

a_v = maximum vertical acceleration, (m/s²), being the coupled motion response applicable to the tank in question.

The vertical acceleration term only applies to transit conditions. For conditions with the deck elevated a_v may be taken equal to zero.

$\gamma_{f,G,Q}$ = partial load factor for permanent and functional loading, see Sec.5 Table A1

$\gamma_{f,E}$ = partial load factor for environmental loads, see Sec.5 Table A1

Descriptions and requirements related to different tank arrangements are given in DNV-OS-D101 Ch.2 Sec.3 C300.

A special tank filling design condition shall be checked according to ULS loading combination a) for tanks where the air-pipe may be filled during filling operations. The following additional internal design pressure conditions shall be used:

$$P_d = (\rho g_0 h_{op} + P_{dyn}) \gamma_{f,G,Q} \quad (\text{kN/m}^2)$$

P_{dyn} = pressure (kN/m²) due to flow through pipes, minimum 25 kN/m²

Guidance note:

This internal pressure need not to be combined with extreme environmental loads. Normally only static global response need to be considered.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

305 Requirements for testing of tank tightness and structural strength are given in DNV-OS-C401 Ch.2 Sec.4.

D. Environmental Loads

D 100 General

101 General considerations for environmental loads are given in DNV-OS-C101 Sec.3 E and F, and in Classification Note 30.5.

102 Combinations of environmental loads are stated in DNV-OS-C101 Sec.3 Table F1.

D 200 Wind loads

201 In conjunction with maximum wave forces the sustained wind velocity, i.e. the 1 minute average velocity, shall be used. If gust wind alone is more unfavourable than sustained wind in conjunction with wave forces, the gust wind velocity shall be used. For local load calculations gust wind velocity shall be used.

202 Formulas for calculation of wind loads may be taken from Classification Note 30.5 Sec.5.

203 Applicable shape coefficients for different structure parts are given in Table D1. For shapes or combination of shapes which do not readily fall into the categories in Table D1 the formulas in Classification Note 30.5 Sec.5 should be applied.

Table D1 Shape coefficient	
Type of structure or member	C_s
Hull, based on total projected area	1.0
Deckhouses, jack-frame structure, sub-structure, draw-works house, and other above deck blocks, based on total projected area of the structure.	1.1
Leg sections projecting above the jack-frame and below the hull	See Classification Note 30.5.
Isolated tubulars, (e.g. crane pedestals, etc.)	0.5
Isolated structural shapes, (e.g. angles, channels, boxes, I-sections), based on member projected area	1.5
Derricks, crane booms, flare towers (open lattice sections only, not boxed-in sections)	According to Classification Note 30.5 or by use of the appropriate shape coefficient for the members concerned applied to 50% of the total projected area.

204 For local design the pressure acting on vertical external bulkheads exposed to wind shall in general not be taken less than 2.5 kN/m².

205 For structures being sensitive to dynamic loads, for instance tall structures having long natural period of vibration, the stresses due to the gust wind pressure considered as static shall be multiplied by an appropriate dynamic amplification factor.

206 The possibility of vibrations due to instability in the flow pattern induced by the structure itself should also be considered.

D 300 Waves

301 The basic wave load parameters and response calculation methods in this standard shall be used in a wave load anal-

ysis where the most unfavourable combinations of height, period and direction of the waves are considered.

302 The liquid particle velocity and acceleration in regular waves shall be calculated according to recognised wave theories, taking into account the significance of shallow water and surface elevation.

Linearised wave theories may be used when appropriate. In such cases appropriate account shall be taken of the extrapolation of wave kinematics to the free surface.

303 The wave design data shall represent the maximum wave heights specified for the unit, as well as the maximum wave steepness according to the unit design basis.

The wave lengths shall be selected as the most critical ones for the response of the structure or structural part to be investigated.

Guidance note:

Practical information in respect to wave conditions, including wave steepness criteria and wave "stretching", is documented in Classification Note 30.5, Sec.3.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

304 For a deterministic wave analysis using an appropriate non-linear wave theory for the water depth, i.e. Stokes' 5th or Dean's Stream Function, the fluid velocity of the maximum long-crested 100 year wave may be multiplied with a kinematic reduction factor of 0.86. The scaling of the velocity shall be used only in connection with hydrodynamic coefficients defined according to 503, i.e. $C_D \geq 1.0$ for submerged tubular members of self-elevating units.

Guidance note:

The kinematics reduction factor is introduced to account for the conservatism of deterministic, regular wave kinematics traditionally accomplished by adjusting the hydrodynamic properties.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 400 Current

401 Characteristic current design velocities shall be based upon appropriate consideration of velocity and height profiles. The variation in current profile with variation in water depth, due to wave action shall be appropriately accounted for.

Guidance note:

Practical information in respect to current conditions, including current stretching in the passage of a wave, is documented in Classification Note 30.5 Sec.4.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 500 Wave and current loads

501 Wave and current loads should be calculated using Morison's equation.

Guidance note:

For information regarding use of Morison's equation see Classification Note 30.5, Sec.6.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

502 Vector addition of the wave and current induced particle velocities should be used for calculation of the combined wave and current drag force. If available, computations of the total particle velocities and acceleration based on more exact theories of wave and current interaction may be preferred.

503 Hydrodynamic coefficients for circular cylinder in oscillatory flow with in-service marine roughness, and for high values of the Keulegan-Carpenter number, i.e. $K_C > 37$, may be

taken as given in Table D2.

Table D2 Hydrodynamic coefficients		
Surface condition	Drag coefficient $C_D(k/D)$	Inertia coefficient $C_M(k/D)$
Multiyear roughness $k/D > 1/100$	1.05	1.8
Mobile unit (cleaned) $k/D < 1/100$	1.0	1.8
Smooth member $k/D < 1/10000$	0.65	2.0
The Keulegan-Carpenter number is defined by: $K_c = \frac{U_m T}{D}$ k = the roughness height D = the member diameter U_m = the maximum orbital particle velocity T = the wave period More detailed formulations for C_D of tubular members depending on surface condition and Keulegan-Carpenter number can be found in Classification Note 30.5 Sec.6.		

504 The roughness for a “mobile unit (cleaned)” applies when marine growth roughness is removed between submer-sion of members.

505 The smooth values may apply above MWL + 2 m and the rough values below MWL + 2 m, where MWL is the mean still water level, as defined in Classification Note 30.5, Figure 4-2.

506 The above hydrodynamic coefficients apply both for deterministic wave analyses when the guidance given in 304 is followed and for stochastic wave analysis.

507 Assumptions regarding allowable marine growth shall be stated in the basis of design.

508 For non-tubular members the hydrodynamic coeffi-cients should reflect the actual shape of the cross sections and member orientation relative to the wave direction.

Guidance note:

Hydrodynamic coefficients relevant to typical self-elevating unit chord designs are stated in Classification Note 30.5 Sec.5 and Classification Note 31.5 Sec.4.5. See also SNAME 5-5A.

Equivalent single beam stiffness parameters for lattice-type legs may be obtained from Classification Note 31.5, Sec.5.6.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

D 600 Sea pressures during transit

601 Unless otherwise documented the characteristic sea pressure acting on the bottom, side and weather deck of a self-elevating unit in transit condition should be taken as:

$$P_d = P_s \gamma_{f, G, Q} + P_e \gamma_{f, E}$$

where the static pressure is:

$$P_s = \rho g_0 (T_{TH} - z_b) \quad (\text{kN/m}^2) \quad \text{for } z_b \leq T_{TH}$$

$$P_s = 0 \quad (\text{kN/m}^2) \quad \text{for } z_b > T_{TH}$$

The dynamic pressure for sides and bottom is:

$$P_e = 0.07 \rho g_0 L \quad (\text{kN/m}^2) \quad \text{for } z_b \leq T_{TH}$$

$$P_e = \rho g_0 (T_{TH} + 0.07 L - z_b) \quad (\text{kN/m}^2) \quad \text{for } z_b > T_{TH}$$

and for weather decks:

$$P_e = \rho g_0 0.75 D_B 0.07 L z_b \quad (\text{kN/m}^2)$$

$$P_e \geq 6.0 \quad (\text{kN/m}^2)$$

T_{TH} = heavy transit draught (m) measured vertically from the moulded baseline to the uppermost transit waterline

z_b = vertical distance in m from the moulded baseline to the load point.

D_B = depth of barge (m)

L = greater of length of breadth (m)

602 In cases where pressure difference is investigated, i.e. transit condition, the pressures shall be combined in such a way that the largest pressure difference is used for design.

603 In case of pressure on both sides of bulkheads, the load factor shall be applied on the pressure difference. The case of a “permanently filled” tank being empty shall also be consid-ered.

D 700 Heavy components during transit

701 The forces acting on supporting structures and lashing systems for rigid units of cargo, equipment or other structural components should be taken as:

$$P_{Vd} = (g_0 \gamma_{f, G, Q} \pm a_v \gamma_{f, E}) M \quad (\text{kN})$$

$$P_{Hd} = a_h \gamma_{f, E} M \quad (\text{kN})$$

a_v = vertical acceleration (m/s^2)

a_h = horizontal acceleration (m/s^2)

M = mass of cargo, equipment or other components (ton)

P_{Vd} = vertical design force

P_{Hd} = horizontal design force.

For units exposed to wind, a horizontal force due to the design gust wind shall be added to P_{Hd} .

Guidance note:

For self-elevating units in transit condition, a_h and a_v need not be taken larger than $0.5 g_0$ (m/s^2).

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

E. Deformation Loads

E 100 General

101 Deformation loads caused by inflicted deformations, such as temperature loads, built-in deformations, etc. should be considered as appropriate.

Further details and description of deformation loads are given in DNV-OS-C101, Sec.3 H.

E 200 Displacement dependent loads

201 Load effects that are a consequence of the displacement of the unit in the elevated condition shall be accounted for. Such effects are due to the first order sway (P -delta), and its enhancement due to the increased flexibility of the legs in the presence of axial loads, i.e. Euler amplification.

F. Accidental Loads

F 100 General

101 The following ALS events shall be considered in respect to the structural design of a self-elevating unit:

- collision
- dropped objects (e.g. from crane handling)
- fire
- explosion
- unintended flooding during transit.

102 Requirements and guidance on accidental loads are given in DNV-OS-C101 and generic loads are given in DNV-OS-A101.

G. Fatigue Loads

G 100 General

101 Repetitive loads, which may lead to possible significant fatigue damage, shall be evaluated. The following listed sources of fatigue loads shall, where relevant, be considered:

- waves (including loads caused by slamming and variable (dynamic) pressures)
- wind (especially when vortex induced vibrations may occur)
- currents (especially when vortex induced vibrations may occur)
- mechanical vibration (e.g. caused by operation of machinery)
- mechanical loading and unloading (e.g. due to jacking or crane operations).

The effects of both local and global dynamic response shall be properly accounted for when determining response distributions related to fatigue loads.

102 Further considerations with respect to fatigue loads are given in DNV-RP-C203.

H. Combination of Loads

H 100 General

101 Load combinations for the design limit states are, in general given in DNV-OS-C101 Sec.3. Specific load factors for self-elevating units for the ULS are given in Sec.5.

102 Structural strength shall be evaluated considering all relevant, realistic load conditions and combinations. Scantlings shall be determined on the basis of criteria that combine, in a rational manner, the effects of relevant global and local responses for each individual structural element.

103 A sufficient number of load conditions shall be evaluated to ensure that the characteristic largest (or smallest) response, for the appropriate return period, has been established.

Guidance note:

For example, maximum global, characteristic responses for a self-elevating unit may occur in environmental conditions that are not associated with the characteristic, largest, wave height. In such cases, wave period and associated wave steepness parameters are more likely to be governing factors in the determination of maximum and minimum responses.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

SECTION 5 ULTIMATE LIMIT STATES (ULS)

A. General

A 100 General

101 The ULS capacity of the structure shall be checked according to the LRFD format. General considerations with respect to definition of the design format, combination of loads, methods of analysis and capacity checks for the ULS are given in DNV-OS-C101.

102 Both global and local capacity shall be checked with respect to ULS. The global and local stresses shall be combined in an appropriate manner.

103 Analytical models shall adequately describe the relevant properties of loads, stiffness, displacement, satisfactorily account for the local system, effects of time dependency, damping, and inertia.

104 Two sets of design load combinations, a) and b) shall be checked. Partial load factors for ULS checks of self-elevating units according to the present standard are given in Table A1.

Table A1 Load factors - Ultimate Limit States			
Combination of design loads	Load categories		
	Permanent and variable functional loads, $\gamma_{f,G,Q}$	Environmental loads, $\gamma_{f,E}$	Deformation loads, $\gamma_{f,D}$
a	1.2 ¹⁾	0.7	1.0
b	1.0	1.2	1.0

1) If the load is not well defined with an upper possible limit, e.g. masses with certain uncertainty, the coefficient should be increased to 1.3.

105 The loads shall be combined in the most unfavourable way, provided that the combination is physically feasible and permitted according to the load specifications. For permanent and variable functional loads, a load factor of 1.0 shall be used in load combination a) where this gives the most unfavourable response.

106 The material factor γ_M for ULS yield check should be 1.15 for steel structural elements. Material factors γ_M for ULS buckling checks and bolt connections are given in DNV-OS-C101 Sec.5. Material factors γ_M for ULS weld connections are given in DNV-OS-C101 Sec.9.

A 200 Global capacity

201 Gross scantlings may be utilised in the calculation of hull structural strength, provided a corrosion protection system in accordance with DNV-OS-C101 Sec.10 is installed and maintained.

202 Ultimate strength capacity check shall be performed for all structural members contributing to the global and local strength of the self-elevating unit. The structures to be checked include, but are not limited to, all plates and continuous stiffeners in the following:

- main load bearing plating in mat and spudcan type footings
- all leg members in truss type legs
- outer plating in column type legs
- jackhouse and supporting structure
- main bearing bulkheads, frameworks and decks in the hull structure
- girders in the hull structure.

B. Structural Capacity

B 100 General

101 Design principles for strength analysis are given in DNV-OS-C101 Sec.5 and Classification Note 31.5.

102 Structural members shall be checked for the most unfavourable combinations of loadings. Girders, pillars, bulkheads, decks and other plate panels shall be checked for relevant combinations of global and local stresses. Buckling strength analysis shall be based on the characteristic buckling strength for the most unfavourable buckling mode.

Guidance note:

Acceptable calculation methods with respect to buckling strength are given in DNV-RP-C201, DNV-RP-C202 and Classification Note 30.1 Sec.2.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

103 Initial imperfections in structural members shall be accounted for. For lattice leg structure this will include imperfections for single beam elements as well as for complete leg assembly.

B 200 Footing strength

201 In the elevated condition account shall be taken of the loads transferred from the legs and the corresponding seabed reaction. The bottom mat or spudcan structure shall be designed to facilitate proper diffusion of these loads.

202 High stress concentrations at the connection between leg and mat or spudcan are to be avoided as far as possible.

203 The effect of an uneven distribution of critical contact stresses over the foundation area is to be examined taking into account a maximum eccentricity moment from the soil resulted from 204, uneven seabed conditions and scouring.

204 For separate type spudcans the maximum design eccentricity moment M_{ed} should normally not be taken less than:

$$M_{ed} = 0.5 F_{vd} R$$

The corresponding critical design contact pressure q_d should not be taken less than:

$$q_d = \frac{F_{vd}}{R^2}$$

F_{vd} = maximum design axial load in the leg accounting for functional loads and environmental overturning loads, including load factors

R = equivalent radius of spudcan contact area

For other types of bottom support, e.g. mats special considerations should be made.

205 For internal compartments which are not freely vented to the sea when the mat or spudcan is resting on the seabed, the design loads shall include a head of water equal to the design water level as well as any effects of wave pressure.

B 300 Leg strength

301 The boundary conditions for the legs at the seabed shall be varied within realistic upper and lower limits when the scantlings of the legs are determined. The variation in boundary conditions shall take into account uncertainties in the estimation of soil properties, non-linear soil-structure interaction, effects due to repeated loadings, possible scouring, etc.

302 When determining the forces and moments in the legs, different positions of the hull supports along the legs shall be considered.

303 Due attention shall be paid to the position and duration of load transfer between the leg and hull, including the shear force in the leg between supporting points in the hull structure.

304 Lattice-type legs shall be checked against overall buckling, buckling of single elements and punching strength of the nodes, see DNV-OS-C101 Sec.5.

305 Bottom impact forces occurring during installation and retrieval conditions shall be satisfactorily accounted in the design.

Guidance note:

A simplified analytical methodology relevant to installation and retrieval conditions is described in Classification Note 31.5.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

B 400 Jackhouse support strength

401 Special attention shall be paid to the means for the leg

support, the jackhouses, the support of the jackhouse to the main hull, and the main load transfer girders between the jackhouses.

B 500 Hull strength

501 Scantlings of the hull shall be checked for the transit conditions with external hydrostatic pressure and inertia forces on the legs as well as for the pre-loading and elevated conditions, see DNV-OS-C101 Sec.5.

C. Scantlings and Weld Connections

C 100 General

101 Minimum scantlings for plate, stiffeners and girders are given in DNV-OS-C101 Sec.5.

102 The requirements for weld connections are given in DNV-OS-C101 Sec.9.

SECTION 6 FATIGUE LIMIT STATES (FLS)

A. General

A 100 General

101 General requirements for the FLS are given in DNV-OS-C101 Sec.6. Guidance concerning fatigue life calculation may be found in DNV-RP-C203 and Classification Note 31.5 Sec.7.

102 The design fatigue life of the unit shall be minimum 20 years.

103 For units intended to follow normal inspection requirements according to class requirements, i.e. 5 yearly inspections in dry dock or sheltered waters, a Design Fatigue Factor (DFF) of 1.0 may be applied for accessible members. For not accessible members DFF shall be applied to structural elements according to the principles in DNV-OS-C101.

104 Units intended to stay on location for prolonged survey period, i.e. without planned dry dock or sheltered water inspection, shall comply with the requirements given in Appendix A.

105 Assumptions related to the resistance parameters adopted in the fatigue design, e.g. with respect to corrosion protection, shall be consistent with the unit's in-service inspection and maintenance plans (see DNV-RP-C203).

106 Local effects, for example, due to:

- slamming
- sloshing
- vortex shedding
- dynamic pressures

shall be included in the fatigue damage assessment when relevant.

107 In the assessment of fatigue resistance, relevant consideration shall be given to the effects of stress concentrations, including those occurring as a result of:

- fabrication tolerances, including due regard to tolerances in way of connections involved in fabrication sequences or section joints
- cut-outs
- details at connections of structural sections (e.g. cut-outs to facilitate construction welding)
- attachments.

108 Local, detailed finite element analysis of critical connections (e.g. leg and footing connection) should be performed in order to identify local stress distributions, appropriate SCFs, and/or extrapolated stresses to be utilised in the fatigue evaluation. Dynamic stress variations through the plate thickness shall be checked and considered in such evaluations when relevant, see DNV-RP-C203 Sec.2 for further details.

109 Principal stresses (see DNV-RP-C203 Sec.2.2) should be utilised in the evaluation of fatigue responses.

B. Fatigue Analysis

B 100 General

101 The required models and methods for fatigue analysis for self-elevating units or jack-ups are dependent on type of operation, environment and design type of the unit. For units operating at deeper waters where the first natural periods are in a range with significant wave energy, e.g. for natural periods higher than 3 s, the dynamic structural response need to be con-

sidered in the fatigue analysis.

B 200 World-wide operation

201 For world wide operation the analyses shall be performed utilising environmental data (e.g. scatter diagram, spectrum) given in Classification Note 30.5. The North Atlantic scatter diagram shall be utilised.

B 300 Restricted operation

301 The analyses shall be performed utilising relevant site specific environmental data for the area(s) the unit will be operated. The restrictions shall be described in the operation manual for the unit.

B 400 Simplified fatigue analysis

401 Simplified fatigue analysis may be performed in order to establish the general acceptability of fatigue resistance, or as a screening process to identify the most critical details to be considered in a stochastic fatigue analysis, see B500.

402 Simplified fatigue analyses should be performed utilising appropriate conservative design parameters. Normally a two-parameter, Weibull distribution (see DNV-RP-C203 Sec.2.14.) may be utilised to describe the long-term stress range distribution, giving the following extreme stress range:

$$\Delta\sigma_{n_0} = \frac{(\ln(n_0))^{\frac{1}{h}}}{(\text{DFF})^{\frac{1}{m}}} \left[\frac{\bar{a}}{n_0 \Gamma\left(1 + \frac{m}{h}\right)} \right]^{\frac{1}{m}}$$

- n_0 = the total number of stress variations during the lifetime of the structure
- $\Delta\sigma_{n_0}$ = extreme stress range that is exceeded once out of n_0 stress variations.
The extreme stress amplitude $\Delta\sigma_{\text{amp1}_n_0}$ is thus given by $(\Delta\sigma_{n_0} / 2)$
- h = the shape parameter of the Weibull stress range distribution, see e.g. Classification Note 31.5 Sec.7.3
- a = the intercept of the design S-N curve with the log N axis, see DNV-RP-C203 Sec.2.3
- $\Gamma(1+m/h)$ = is the complete gamma function, see DNV-RP-C203 Sec.2.14
- m = the inverse slope of the S-N curve, see DNV-RP-C203 Sec.2.14
- DFF = Design Fatigue Factor.

403 When the simplified fatigue evaluation involves utilisation of the dynamic stress responses resulting from the global analysis, e.g. 100 years, the response should be suitably scaled to the return period of the basis, minimum fatigue life of the unit. In such cases, scaling may be undertaken utilising the appropriate factor found from the following:

$$\Delta\sigma_{n_0} = \Delta\sigma_{n_i} \left[\frac{\log n_0}{\log n_i} \right]^{\frac{1}{h}}$$

- n_i = the number of stress variations in i years appropriate to the global analysis

$\Delta\sigma_{n_i}$ = the extreme stress range that is exceeded once out of n_i stress variations.

B 500 Stochastic fatigue analysis

501 Stochastic fatigue analyses shall be based upon recognised procedures and principles utilising relevant site specific data or world wide environmental data.

502 Simplified fatigue analyses should be used as a “screening” process to identify locations for which a detailed, stochastic fatigue analysis should be undertaken.

503 Fatigue analyses shall include consideration of the directional probability of the environmental data. Providing that it can be satisfactorily checked, scatter diagram data may be considered as being directionally specific. Scatter diagram for world wide operations (North Atlantic scatter diagram) is given in Classification Note 30.5. Relevant wave spectra and energy spreading shall be utilised. Normally a Pierson-Moskowitz spectrum and a \cos^4 spreading function is utilised in the evaluation of self-elevating units. Further details are given in Classification Note 31.5.

504 Structural response shall be determined based upon analyses of an adequate number of wave directions. Generally a maximum radial spacing of 15 degrees should be considered. Transfer functions should be established based upon consideration of a sufficient number of periods, such that the number, and values of the periods analysed:

- adequately cover the wave data
- satisfactorily describe transfer functions at, and around, the wave ‘cancellation’ and ‘amplifying’ periods (consideration should be given to take account that such ‘cancellation’ and ‘amplifying’ periods may be different for different elements within the structure)
- satisfactorily describe transfer functions at, and around, the relevant excitation periods of the structure.

505 Stochastic fatigue analyses utilising simplified structural model representations of the unit (e.g. a space frame model) may form basis for identifying locations for which a stochastic fatigue analysis, utilising a detailed model of the structure, should be performed (e.g. at critical intersections).

SECTION 7 ACCIDENTAL LIMIT STATES (ALS)

A. General

A 100 General

101 ALS shall be assessed for relevant accidental events. Principally satisfactory protection against accidental damage should be obtained by the following two means:

- low damage probability
- acceptable damage consequences.

Further information about safety principles and arrangements with respect to design towards accidental events are given in DNV-OS-A101.

102 The capability of the structure to redistribute loads during and after accidents should be considered when designing the unit.

After damage requiring immediate repair, the unit is to resist functional and environmental loads corresponding to a return period of one year.

Guidance note:

Energy absorption by impact types of accidental events requires the structure to behave in a ductile manner. Measures to obtain adequate ductility are:

- make the strength of connections of primary members in excess of that of the member
- provide redundancy in the structure, so that alternate load redistribution paths may be developed
- avoid dependence on energy absorption in slender members with a non-ductile post buckling behaviour
- avoid pronounced weak sections and abrupt change in strength or stiffness
- use non-brittle materials.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

103 The loads and consequential damage due to accidental events such as:

- collision
- dropped objects (e.g. from crane handling)
- fire
- explosion
- unintended flooding during transit

shall be considered to avoid loss of floatability or capsizing during transit, on-bottom instability in elevated operation or survival conditions, pollution or loss of human life. Requirements for compartmentation and floating stability are given in DNV-OS-C301.

104 Analysis and requirements to satisfy strength criteria are given in the present standard and in DNV-OS-C101 Sec.7.

105 The damage consequences of accidental events other than those listed in 103 shall if relevant be specially considered in each case applying an equivalent standard of safety.

B. Collisions

B 100 General

101 Collision by a supply vessel against a leg of a self-elevating unit is to be considered for all elements that may be hit either by sideways, bow or stern collision. The vertical extent of the collision zone is to be based on the depth and draught of

visiting supply vessels.

Guidance note:

Simplified procedures for calculation of vessel impact on self-elevating unit legs may be found in Classification Note 31.5.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

102 A collision will normally only cause local damage of the leg. However, the global strength and overturning stability of the unit shall also be checked. With lattice type legs the damaged chord or bracing and connections may be assumed to be non-effective for check of residual strength of the unit after collision.

103 Assessment of dynamic effects and non-linear structural response (geometrical and material) should be performed as part of the impact evaluation.

C. Dropped Objects

C 100 General

101 Critical areas for dropped objects shall be determined on the basis of the actual movement of potential dropped objects (e.g. crane or other lifting operation mass) relative to the structure of the unit itself. Where a dropped object is a relevant accidental event, the impact energy shall be established and the structural consequences of the impact assessed.

102 A dropped object impact against a chord or bracing will normally cause complete failure of the element or its connections. These parts should then be assumed to be non-effective for the check of the residual strength of the unit after the dropped object impact.

103 Critical areas for dropped objects are to be determined on the basis of the actual movement of loads assuming a minimum drop direction within an angle with the vertical direction:

- 5 degrees in air
- 15 degrees in water.

Dropped objects are to be considered for vital structural elements of the unit within the areas given above.

D. Fires

D 100 General

101 The structure that is subjected to a fire shall have sufficient structural capacity before evacuation has occurred. The following fire scenarios shall be considered:

- jet fires
- fire inside or on the hull
- fire on the sea surface.

102 Further requirements concerning accidental limit state events involving fire is given in DNV-OS-A101.

103 Structural assessment with respect to fire may be omitted provided fire protection requirements made in DNV-OS-D301 are met.

E. Explosions

E 100 General

101 With respect to design loads resulting from explosions, one or more of the following design philosophies are relevant:

- ensure that hazardous locations are located in unconfined (open) locations and that sufficient shielding mechanisms (e.g. blast walls) are installed
- locate hazardous areas in partially confined locations and design utilising the resulting, relatively small overpressures
- locate hazardous areas in enclosed locations and install pressure relief mechanisms (e.g. blast panels) and design for the resulting overpressure.

102 As far as practicable, structural design accounting for large plate field rupture resulting from explosion loads should be avoided due to the uncertainties of the loads and the consequences of the rupture itself.

103 Structural support of blast walls and the transmission of the blast loads into main structural members shall be evaluated when relevant.

F. Unintended Flooding

F 100 General

101 For the transit condition, structural effects as a results of heeling of the unit after damage flooding as described in DNV-OS-C301 shall be accounted for in the structural strength assessment. Boundaries which shall remain watertight after unintended flooding, shall be checked for external water pressure.

102 The unit shall be designed for environmental condition corresponding to 1 year return period after damage flooding, see DNV-OS-C101.

Guidance note:

The environmental loads may be disregarded if the material factor γ_M is set to 1.33.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

103 Local exceedance of the structural resistance level may be acceptable provided redistribution of forces due to yielding, buckling and fracture is accounted for.

104 Wave pressure, slamming forces and green sea shall be accounted for in all relevant areas. Local damage may be accepted provided progressive structural collapse and damage of vital equipment is avoided.

105 Position of air-intakes and openings to areas with vital equipment which need to be available during an emergency situation e.g. emergency generators, shall be considered taking into account the wave elevation in a 1 year storm condition.

SECTION 8 SPECIAL CONSIDERATIONS

A. General

A 100 General

101 Some special items to be considered in relation to robust design and safe operation of self-elevating units are described in this section.

B. Pre-load Capacity

B 100 General

101 Minimum required pre-load capacity with reference to the global strength and the seabed design assumptions for units with separate footings shall be accounted for in the design.

Guidance note:

It should be noted that actual soil conditions at operation sites may require higher pre-loads than those set up by the leg strength, e.g. to secure against sudden penetration.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

102 The assessment of pre-load capacity given in 103 and 104 should be performed with the characteristic functional and environmental loads, i.e. without load factors.

103 Units with separate footings which are designed for a pinned leg-bottom connection are to have a capability to pre-load the legs up to at least 100% of the maximum design axial loads in the legs accounting for functional loads and environmental overturning loads.

For units that shall operate in soil conditions where exceedance of the soil capacity will result in large penetrations, a pre-load higher than the maximum survival axial load case axial load will be required. Examples of such soils are generally soft clays, or conditions where hard soils are underlain by softer soils and there is a risk of a punch-through failure.

A recommended approach for determination of required pre-load is given in Classification Note 30.4.

104 Units with separate footings where the design is based on a specified moment restraint of the legs at the seabed are to have a capability to pre-load the legs up to a level which shall account for the maximum design axial loads in the legs due to functional loads and environmental overturning loads plus the specified moment restraint at the bottom.

In lieu of a detailed soil/structure interaction analysis the required pre-load may in this case be determined by the following factor:

For cohesive soils, e.g. clay:

$$\frac{F_{VP}}{F_V} = \frac{1}{1 - \frac{2\sqrt{A}M_U}{\pi R^2 F_V}}$$

For cohesionless soils, e.g. sand:

$$\frac{F_{VP}}{F_V} = \left(\frac{1}{1 - \frac{2\sqrt{A}M_U}{\pi R^2 F_V}} \right)^2$$

F_{VP} = minimum required pre-load on one leg

F_V = maximum design axial load in the leg accounting for functional loads and environmental overturning loads

M_U = minimum design moment restraint of the leg at the seabed

A = area of spudcan in contact with soil

R = equivalent radius of spudcan contact area.

105 For cohesionless soils, the above requirement to pre-load capacity may be departed from in case where a jetting system is installed which will provide penetration to full soil contact of the total spudcan area.

106 The potential of scour at each location should be evaluated. If scour takes place, the beneficial effect of pre-loading related to moment restraint capacity may be destroyed. At locations with scour potential, scour protection should normally be provided in order to rely on a permanent moment restraint.

C. Overturning Stability

C 100 General

101 The safety against overturning is determined by the equation:

$$\gamma_s \leq \frac{M_s}{M_O}$$

M_O = overturning moment, i.e. caused by environmental loads

M_S = stabilising moment, i.e. caused by functional loads

γ_s = safety coefficient against overturning
= 1.1.

102 The stabilising moment due to functional loads shall be calculated with respect to the assumed axis of rotation, and with the unit's lateral deflections taken into consideration.

For self-elevating units with separate footings the axis of rotation may, in lieu of a detailed soil-structure interacting analysis, be assumed to be a horizontal axis intersecting the axis of two of the legs. It may further be assumed that the vertical position of the axis of rotation is located at a distance above the spudcan tip equivalent to the lesser of:

- half the maximum predicted penetration or
- half the height of the spudcan.

For self-elevating units with mat support, the location of the axis of rotation may have to be specially considered.

103 The overturning moment due to wind, waves and current should be calculated with respect to the axis of rotation defined in 102.

The overturning stability is to be calculated for the most unfavourable direction and combination of environmental and functional loads according to the load plan for the unit. The dynamic amplification of the combined wave and current load effect shall be taken into account.

104 The lower ends of separate legs are to be prevented from sideway slipping by ensuring sufficient horizontal leg and soil support.

D. Air Gap

D 100 General

101 Clearance between the hull structure and the wave crest is normally to be ensured for the operating position.

102 The requirement to the length of the leg is that the distance between the lower part of the deck structure in the operating position and the crest of the maximum design wave, including astronomical and storm tides, is not to be less than 10% of the combined storm tide, astronomical tide and height

of the design wave above the mean low water level, or 1.2 m, whichever is smaller. Expected subsidence of the structure is to be taken into account.

103 Crest elevation above still water level is given in Fig.1.

104 A smaller distance may be accepted if wave impact forces on the deck structure are taken into account in the strength and overturning analysis.

Clearance between the structure and wave is to be ensured in floating condition for appurtenances such as helicopter deck, etc.

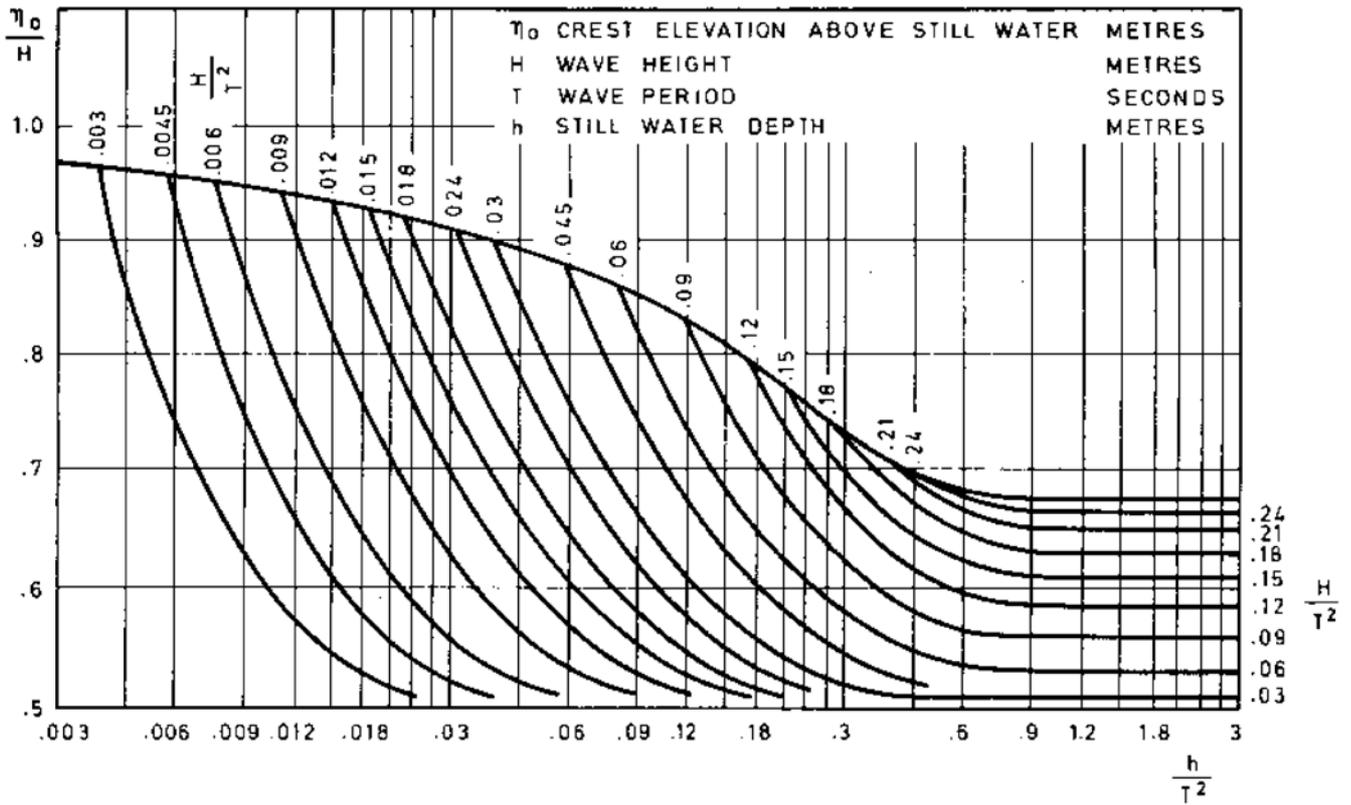

Figure 1
Crest elevation

APPENDIX A PERMANENTLY INSTALLED SELF-ELEVATING UNITS

A. Introduction

A 100 General

101 The requirements and guidance given in this Appendix are supplementary requirements for units that are intended to stay on location for prolonged periods, normally more than 5 years.

102 The requirements apply to all types of self-elevating units.

103 Permanently installed self-elevating units shall be designed or documented for the site specific environmental and soil conditions. Fatigue properties and facilities for survey on location shall be specially considered.

104 Adequate corrosion protection shall be implemented to cover the entire prolonged operation period.

B. Fatigue

B 100 General

101 Design Fatigue Factors (DFF) are introduced as fatigue safety factors. DFF shall be applied to structural elements according to the principles in DNV-OS-C101.

102 Fatigue safety factors applied for permanently installed self-elevating units shall be given dependent on the criticality of the detail and accessibility for inspection and repair. Special considerations should be made for the leg in the splash zone, submerged parts legs and spudcan, and possible inaccessible parts of the spudcan, see C200.

103 The fatigue analysis should focus on members that are essential to the overall structural integrity of the unit.

Fatigue susceptible areas may include:

- the leg to hull holding system
- the leg members and joints in the vicinity of the upper and lower guides
- the leg members and joints in the splashing zone
- the leg members and joints in the lower part of the leg near the spudcan
- the spudcan to leg connection.

Guidance note:

See DNV-OS-C101 Sec.10 B200 with respect to vertical extent of splash zone.

---e-n-d---of---G-u-i-d-a-n-c-e---n-o-t-e---

C. Inspection and Maintenance

C 100 Facilities for survey

101 Surveys may be carried out on location based on agreed procedures outlined in a maintenance system and survey arrangement, without interrupting the function of the unit. The following matters shall be taken into consideration to be able to carry out surveys on location:

- arrangements and methods for survey of hull, legs and seabed foundation structure
- corrosion protection of hull, legs and seabed foundation structure
- underwater cleaning facilities.

102 The In Service Inspection program (IIP) should reflect possible stress concentrations in critical areas, fatigue criticality, and the previous operational and inspection histories.
